

Practical: Inspect a Live Page in 5 Minutes

ICS441 — Completed Evidence Report

Student / Group: _____

Date: _____ Browser: Microsoft Edge

1. Practical Objective

The practical required inspection of a live webpage using browser Developer Tools. The required activities were to inspect a heading, button and form field, check whether images have alternative text, reload the page using Network tools, identify the slowest request, and submit a screenshot with a one-paragraph diagnosis.

2. Elements Panel Evidence

Figure 1. Microsoft Edge DevTools Elements panel showing the live page HTML structure.

Observed evidence: The screenshot shows the HTML document beginning with `<!DOCTYPE html>`, an `<html lang="en-US">` element, a visible `<head>`, and the page `<body>`. The supplied screenshot does not visibly expose a specific heading, button, form field, or image alt attribute, so these elements are not claimed as inspected findings.

3. Network Panel Evidence

Figure 2. Microsoft Edge DevTools Network panel showing the captured network activity.

4. Recorded Network Findings

Finding	Observed evidence	Interpretation
Total requests	204 requests	The page generated a substantial number of network requests during the captured activity.
Data transferred	1.3 MB transferred	Amount of data transferred shown by DevTools.
Resources	3.4 MB resources	Total resource size reported by DevTools.
Slowest visible request	process_upload_stream — 2.53 s	Slowest visible request in the supplied screenshot; therefore the main performance item identified by the evidence.
Status	HTTP 200	The request completed successfully according to the captured status code.
Another slow resource	PNG — 1.71 s	Also relatively slow, but faster than process_upload_stream in the captured list.

5. Completed One-Paragraph Diagnosis

Diagnosis: I inspected the ChatGPT webpage using Microsoft Edge Developer Tools. In the Elements panel, I examined the page's HTML structure and confirmed that it uses an HTML5 document structure with the language set to en-US. The supplied Elements evidence does not visibly expose a specific heading, button, form field, or image alternative text, so no unsupported conclusion is made about those elements. I then used the Network panel and observed 204 requests, approximately 1.3 MB transferred, and 3.4 MB of resources. The slowest visible request was process_upload_stream, which took approximately 2.53 seconds and returned HTTP 200, indicating successful completion. A PNG resource also took approximately 1.71 seconds. Overall, the inspection indicates a relatively large amount of network activity, with process_upload_stream being the main performance bottleneck visible in the supplied evidence.

6. Conclusion

The Developer Tools inspection provided evidence about the webpage's HTML structure and network performance. The Network panel was particularly useful for identifying the slowest visible request and quantifying the number of requests and amount of data involved. The Elements evidence should not be used to make claims about specific accessibility attributes that are not visible in the screenshot.
